## Question

How wide is the pain threshold for participants taking part in the SPARS A trial?

To answer the question, we calculated the *Tukey Trimean* and bootstrapped 95% confidence interval (CI) for each individual, at each stimulus intensity. Next, we plotted these statistics to show the stimulus range over which each individual's CIs included zero on the SPARS (pain threshold).

To get an idea of the width of the stimulus range that included zero on the SPARS at the group level, we calculated the *Tukey trimean* for each individual, at each stimulus intensity, and then calculated the mean and bootstrapped 95% CI for the group at each stimulus intensity. These data were then plotted to show the stimulus range over which the group's CIs included zero (pain threshold).

The selection of the *tukey trimean* as the measure of central tendency at the individual level was based on the analysis of central tendency reported in the original description of the SPARS (Supplement\_3.pdf). The *Tukey trimean* is defined as the weighted average of the distribution's median and its two quartiles, and is a robust measure of central tendency that unlike a median, takes the spread of the data into account.

$$T_{mean} = \frac{1}{2}(Q_2 + \frac{Q_1 + Q_3}{2})$$

Where:

- $Q_1$  = 25<sup>th</sup> percentile

- $Q_2 = 50^{\text{th}}$  percentile (median)

- $Q_3 = 75^{\text{th}}$  percentile

```
# Define the tri_mean function
tri_mean <- function(x) {
  # Calculate quantiles
  q1 <- quantile(x, probs = 0.25, na.rm = TRUE)[[1]]
  q2 <- median(x, na.rm = TRUE)
  q3 <- quantile(x, probs = 0.75, na.rm = TRUE)[[1]]
  # Calculate trimean
  tri_mean <- (q2 + ((q1 + q3) / 2)) / 2
  # Round to a whole number
  tri_mean <- round(tri_mean)
  return(tri_mean)
}
```

**Note:** No inspection of block and stimulus order effects were undertaken because analysis of these factors in the original description of the SPARS revealed no order effects (Supplement\_4.pdf).

The experimental protocol called for participants to be exposed to 13 stimuli, evenly spaced at 0.25J intervals over the range 1.00J to 4.00J. Each stimulus intensity was applied 8 times, giving a total of 104 exposures (trials). To prevent learning effects, the 104 trials were randomised across 4 experimental blocks (26 trials per block).

---

## Import and inspect data

```
# Import
data <- read_rds('data-cleaned/SPARS_A.rds')

# Inspect
glimpse(data)

```

Group: Crossbar plots of 95% CI of Tukey trimeans for SPARS ratings at each stimulus intensity

- Basic bootstrap 95% CI with 10,000 resamples
- Dashed line: pain threshold | – Grey fill: 95% CI includes zero
