October 2022

#### Abstract

Application of OMP-2020 for toothfish in the Prince Edward Islands vicinity provides a TAC recommendation for the 2022 "fishing" ${ }^{1}$ year of 573.2 tonnes. This is a $4.5 \%$ increase of the previous season's TAC of 548.5 tonnes.

Keywords: OMP, Patagonian toothfish, TAC recommendation

The 2020 OMP (Brandão and Butterworth, 2021)

The algorithm for recommending the TAC for the $y+1$ "fishing" year is specified as:

$$
\begin{equation*}
T A C_{y+1}=T A C_{y}\left[1+\lambda\left(\frac{\mu_{y}^{C P U E}-t *}{t *}\right)\right]\left[1-\gamma\left(\frac{s_{y}^{\text {cum }(r e c a p)}-s_{t}^{*}}{s_{t}^{*}}\right)\right] \tag{1}
\end{equation*}
$$

where

| $T A C_{y}$ | is the TAC recommended for year $y$, |
| :--- | :--- |
| $\mu_{y}^{C P U E}$ | is the mean trotline CPUE for the years $y-4, y-3$ and $y-2$, |
| $s_{y}^{\text {cum(recap })}$ | is the slope of a linear regression of the cumulative number of recaptured tags <br> against time for the years $y-6$ to $y-2$, and |
| $\lambda, \gamma, t *$ and $s_{t}^{*}$ | are control parameters given by: <br> $\lambda=1, \gamma=1, t *=0.760$ and $s_{t}^{*}=44$. |

## Constraints

The MP constrains TACs to a maximum inter-annual change of $10 \%$, so that $T A C_{y+1}$ is adjusted accordingly as:

[^0]\[

T A C_{y+1}=\left\{$$
\begin{array}{cc}
T A C_{y}(1+0.1) & \text { if } T A C_{y+1}>T A C_{y}(1+0.1)  \tag{2}\\
T A C_{y}(1-0.1) & \text { if } T A C_{y+1}<T A C_{y}(1-0.1) \\
T A C_{y+1} & \text { otherwise }
\end{array}
$$\right.
\]

A smoothing of the TAC over its first five years of implementation is also applied, so that the final TAC is given by:

$$
\begin{equation*}
T A C_{y+1}^{\text {final }}=\psi_{y+1} T A C_{y+1} \tag{3}
\end{equation*}
$$

where
$\psi_{y+1} \quad$ is the initial period smoothing factor, given by:

$$
\psi_{y+1}=\left\{\begin{array}{lc}
x & \text { for } y+1 \leq 2025  \tag{4}\\
z & \text { for } 2025<y+1<2030 \\
1 & \text { for } y+1 \geq 2030
\end{array}\right.
$$

where
$1-x$ is the percentage by which the TAC is reduced initially, with $x=0.95$ for OMP-2020, and $z \quad$ reflects a linear increase from $x$ in 2025 to 1 in 2030.

Table 1 provides the GLMM-standardised trotline CPUE estimates (Brandão and Butterworth, 2022), and the cumulative number of tag-recaptures observed which include data up to 2021.

Figure 1 compares the recent observed CPUE index and the cumulative number of recaptured tags to the projections for the Reference Set of Operating Models under OMP-2020. The cumulative number of recaptured tags lies within its $90 \%$ probability envelope, but the recent CPUE index lies above its $90 \%$ probability envelope. However, given the positive result for the most recent CPUE index and the fact that the observed value is not substantially above the probability envelope, together with the resultant TAC increase indicated below, it is considered not necessary to immediately invoke Exceptional Circumstances.

The mean CPUE $\mu_{y}^{C P U E}$ is calculated as:

$$
\mu_{y}^{C P U E}=\frac{1}{3} \sum_{y=2019}^{2021} C P U E_{y}=\frac{0.927+0.689+1.043}{3}=0.886
$$

The slope of the linear regression of the cumulative number of recaptured tags against time $s_{y}^{\text {cum(recap })}$ is calculated by fitting a linear regression to the pairwise series $(2017,107),(2018,138)$, $(2019,149),(2020,171)$ and $(2021,188)$ and is given by $s_{y}^{\text {cum }(\text { recap })}=19.5$.

Thus, the preliminary TAC is given by:

$$
T A C_{2022}=\left(548.5\left[1+1\left(\frac{0.886-0.76}{0.76}\right)\right]\left[1-1\left(\frac{19.5-44}{44}\right)\right]\right)=995.9
$$

However, as the MP constrains the TACs to a maximum inter-annual change of $10 \%$, and also applies an initial smoothing of the TAC, the final TAC is given by:

$$
T A C_{2022}^{\text {final }}=\psi_{y+1}\left(T A C_{2021}(1+0.1)\right)=0.95(548.5(1.1))=573.2
$$

Therefore, the final TAC recommendation for 2022 (i.e. the 2022 "fishing" year) is 573.2 tonnes.
